# Problem Set 7

We will work on the following exercises together during the work sessions on Tuesday, 3 October 2017.

You are strongly encouraged to work together on the exercises, including the homework. You do not have to hand in solutions to these problem sets.

### Problem 1: Exercise 4.1 from [KL]

Say  $\Pi = (\text{Gen}, \text{Mac}, \text{Vrfy})$  is a secure MAC, and for  $k \in \{0, 1\}^n$  the tag-generation algorithm  $\text{Mac}_k$  always outputs tags of length  $t(n)$ . Prove that  $t$  must be super-logarithmic or, equivalently, that if  $t(n) = O(\log n)$  then  $\Pi$  cannot be a secure MAC

**Hint:** Consider the probability of randomly guessing a valid tag.

### Problem 2: Exercise 4.6 from [KL]

Consider the following MAC for messages of length  $\ell(n) = 2n - 2$  using a pseudorandom function  $F$ : On input a message  $m_0 \| m_1$  (with  $|m_0| = |m_1| = n - 1$ ) and key  $k \in \{0, 1\}^n$ , algorithm  $\text{Mac}$  outputs  $t = F_k(0 \| m_0) \| F_k(1 \| m_1)$ . Algorithm  $\text{Vrfy}$  is defined in the natural way. Is  $(\text{Gen}, \text{Mac}, \text{Vrfy})$  secure? Prove your answer.

### Problem 3: Exercise 4.14 from [KL]

Prove that the following modifications of basic CBC-MAC do not yield a secure MAC (even for fixed-length messages):

1.  $\text{Mac}$  outputs all blocks  $t_1, \dots, t_\ell$ , rather than just  $t_\ell$ . (Verification only checks whether  $t_\ell$  is correct.)
2. A random initial value is used each time a message is authenticated. That is,  $t_0 \in \{0, 1\}^n$  is chosen uniformly at random rather than being

fixed to  $0^n$ , and the tag is  $\langle t_0, t_\ell \rangle$ . Verification is done in the natural way.

### ★ Problem 4: Exercise 4.15 from [KL]

Show that appending the message length to the *end* of the message before applying basic CBC-MAC does not result in a secure MAC for arbitrary-length messages.
